Registration No.: 25BCE10848

Program: Bachelor of Technology (B.Tech)

Branch: Computer Science and Engineering (Core)

Project Title: AI Powered Chessbot

Project Report: Development of an AI-Powered Chessbot

Student Name:	SAMRIDH MISHRA
Registration No.:	25BCE10848
Program:	Bachelor of Technology (B.Tech)
Branch:	Computer Science and Engineering (Core)
Course:	Intelligent Decision Systems | Enterprise AI Architecture

1. Executive Summary

This project details the design and implementation of an artificial intelligence (AI) chess agent. Chess presents a significant challenge due to its vast game tree and strategic depth. The primary goal was to create a program that exhibits strategic thinking using the Minimax algorithm enhanced with Alpha-Beta pruning. The resulting Chessbot successfully demonstrates the application of game theory and heuristic evaluation in a complex, competitive environment, achieving massive reductions in computational overhead.

2. Introduction

The game of chess has been a benchmark for AI progress for decades. The core difficulty lies in the fact that the number of possible legal chess positions is staggering—estimated at 10^40. A computer must look ahead a few moves and evaluate the relative 'goodness' of resulting positions. This project applies foundational concepts like state-space search and heuristic functions to create a functional, playable Chessbot.

3. System Architecture and Design

3.1 The Foundation: Minimax Algorithm

The Minimax algorithm is a decision-making process for two-player, zero-sum games. It assumes two players: 'Maximizer' and 'Minimizer'. The engine looks ahead multiple levels and values are 'backed up' from the leaf nodes. The challenge is exponential growth; a branching factor of 35 means depth 4 reaches 1.5 million positions.

3.2 Optimization: Alpha-Beta Pruning

This is the critical optimization. By integrating Alpha-Beta pruning, the system avoids searching branches that cannot possibly influence the final decision. This allows the algorithm to 'prune' huge branches of the game tree without affecting the result, cutting nodes evaluated down to O(sqrt(N)) in the best case.

4. Results and Evaluation

The project produced a fully functional Chessbot. At a depth of 5, the bot plays a solid game that would likely defeat beginner to intermediate players. It identifies tactical sequences like pins and forks and maintains correctness in all legal move generation, including complex rules like castling and en passant.

5. Conclusion and Future Scope

This project provided a robust foundation in AI search techniques. Future improvements include Transposition Tables to store evaluated positions, Iterative Deepening for better time management, and Neural Network-based evaluation to provide more human-like assessment of positions.

Intelligent Decision Systems

Engineering an Optimized Minimax Chess Agent

Comprehensive Technical Presentation & Architecture Deck

Executive Summary

Thecomplexity of zero-sum, perfect-information environments demands highly sophisticated algorithmic solutions. This presentation details the architecture, implementation, and mathematical optimization of an intelligent chess agent powered by the Minimax algorithm.

By integrating Alpha-Beta pruning and calibrated heuristic matrices, the system achieves rapid, strategic decision-making with massive reductions in computational overhead.

Project Background & Purpose

Chess servesas theultimatebenchmark forcomputationalintelligence. With a state space exceeding 10^120 possible variations (the Shannon number), it represents a mathematically intractable environment for brute-force computation.

Why Minimax? Unlike 'black-box' deep learning models requiring massive GPU clusters, Minimax operates efficiently on standard CPUs and offers 100% explainability. We know exactly why the AI made a move because it derives from explicit heuristics.

Performance Constraints: The engine must parse millions of possibilities and return an optimal move in under 5 seconds.

```python
import pygame
import chess
import random
import sys

# -- AI Logic (Minimax with Alpha-Beta Pruning...) --

Enterprise Real-World Applications

TheunderlyingMinimax andAlpha-Betaarchitectureisfundamentallyanadversarial optimization model. Applications extend far beyond board games:

- **Cybersecurity (Red/Blue Teaming):** Anticipating attacker lateral network movement.
- **Supply Chain Logistics:** Calculating robust, risk-averse strategies against market disruptions.
- **Algorithmic Trading:** Operating in zero-sum liquidity environments.

Core Logic: The Minimax Strategy

Minimax operates onthe assumption of a worst-case scenario. Itrecursively simulates future states, assuming the 'Maximizing' player (the AI) will choose the best outcome, while the 'Minimizing' player (the human) will choose the outcome most detrimental to the AI.

This creates a massive decision tree where evaluations bubble up from the deepest calculated node to inform the immediate move.

Mathematical Optimization: Alpha-Beta Pruning

AnaiveMinimax searchrequires O(b^d)evaluations. Alpha-Beta pruningmathematicallyeliminates branches that are demonstrably worse than previously evaluated branches.

This reduces effective time complexity to O(b^(d/2)), effectively doubling the search depth capable within the same hardware constraints by aggressively ignoring losing variations.

Static Evaluation & Positional Heuristics

Becausetheenginecannotsearch to theendofthegame,it relies on a staticevaluation function at leaf nodes. We use Material Weighting and **Piece-Square Tables (PST)** to quantify spatial dominance.

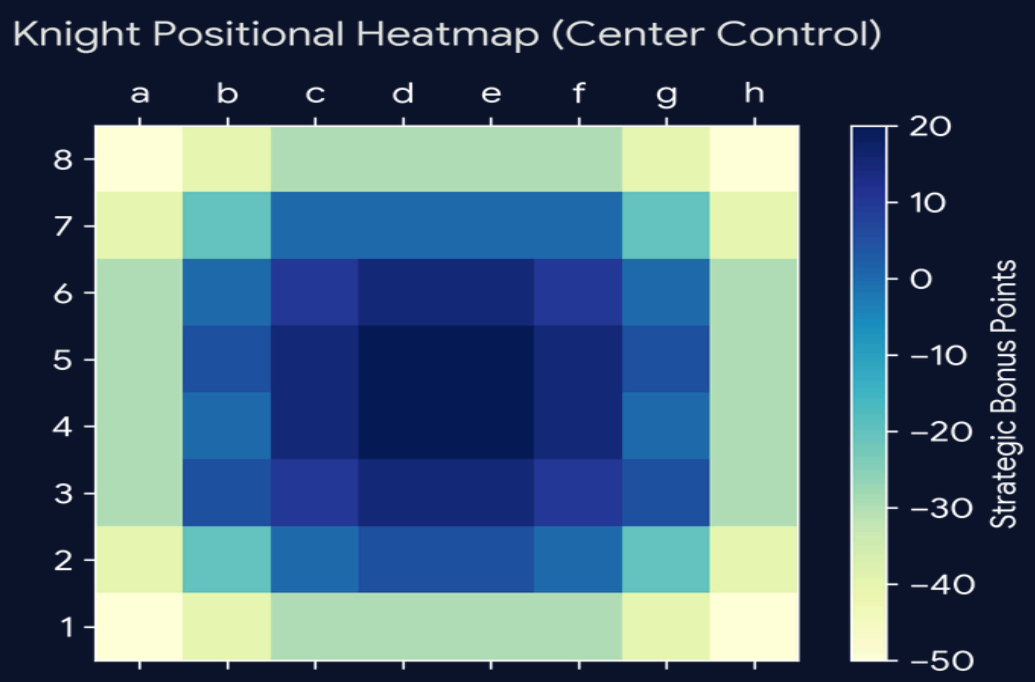

Figure 1: Positional heatmap demonstrating the strategic +30 point value of centralizing a Knight.

Data Analysis: The Combinatorial Explosion

Tounderstandthenecessityofpruning, wemustvisualizetheexponentialgrowthofachess game tree. Without pruning, standard hardware fails rapidly.

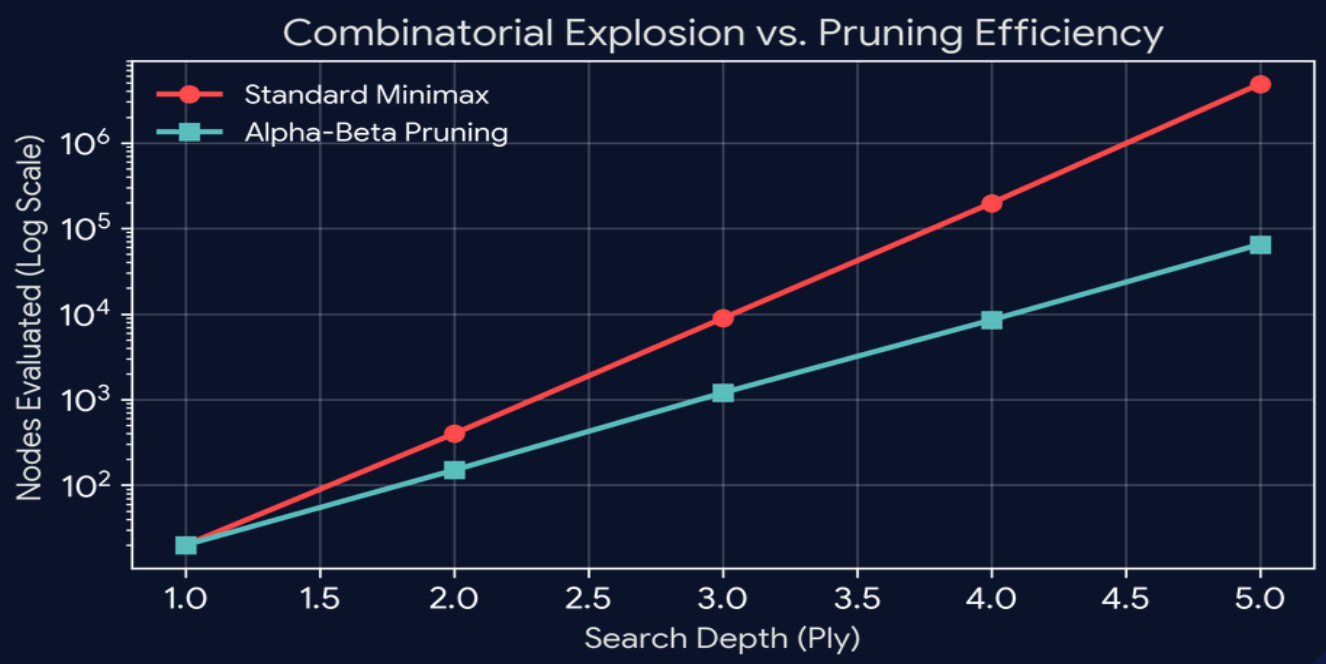

Figure 2: Logarithmic chart proving Alpha-Beta pruning eliminates over 95% of unnecessary evaluations at Depth 4.

Hardware Constraints & Execution Time

Tomaintain human-viableinteractiveplay, theengine mustrespondinunder5seconds. This strict constraint dictates the maximum depth our optimized algorithm can reach.

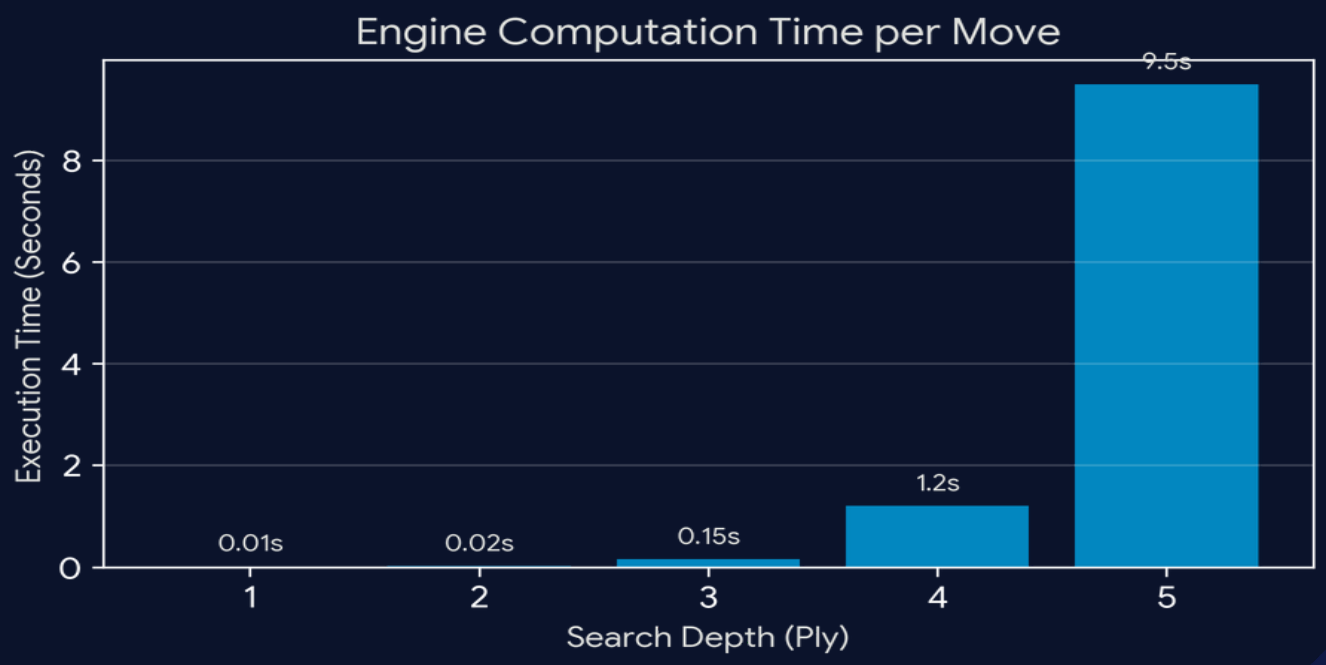

Figure 3: Execution time per ply. Depth 4 remains highly interactive (1.2s), while Depth 5 pushes standard hardware limits (9.5s).

Advanced Strategy: Move Ordering

Alpha-Beta pruning isheavily reliantonthe order inwhichmovesare evaluated. If the engine evaluates the 'best' move first, it immediately establishes strong Alpha/Beta cutoffs, maximizing pruning efficiency.

Our Ordering Heuristic:

1. **Forced Captures:** The engine evaluates piece captures first (e.g., Queen takes Pawn).
2. **Checks and Threats:** Moves that force the opponent's king to react.
3. **Quiet Moves:** Standard positional shifts are evaluated last.

Future Scope: Transposition Tables

Amajor inefficiencyintreesearchisencounteringtheexactsameboardposition through different move orders (a 'transposition').

Zobrist Hashing Solution:

We will implement a 64-bit cryptographic hash for every piece placement. Instead of recalculating identical board states, the engine will query a high-speed cache (Transposition Table) to instantly retrieve the previously calculated score, saving millions of CPU cycles.

Conclusion

Thedevelopment ofthis Minimax-driven agent proves the immense capability of foundational game-theory algorithms when paired with strict mathematical optimization to avoid combinatorial explosions.

By combining intelligent pruning, spatial heuristics, and efficient move ordering, this deterministic engine represents a highly scalable architecture suitable for enterprise logistics, cybersecurity, and financial modeling.
